Custom Table Creation in ServiceNow

Ticket Table and Form Design - Explained

Description

A custom table is created to store and manage ticket-related information in a structured manner. The table is configured with the required fields, auto-numbering, and form layout so that every ticket is uniquely identified and easy to manage. The Form Designer is then used to organize the fields on the form according to the project requirements. All these changes are captured in the current update set (Project Update Set).

Component	Explanation
Custom table	A new database table that holds all ticket records in one standard structure.
Fields	Columns of the table (for example Caller, Description, Category, Subcategory) that store each piece of ticket data.
Auto-numbering	Automatically generates a unique ticket number for every new record.
Form layout	How the fields are arranged on the ticket form, set using Form Designer.
Update set	The created update set appears as Current, so the table and form changes are tracked in it.

Steps Involved

Step	Activity	Explanation	Result
1	Create the custom table	Go to System Definition > Tables > New. Enter the label (for example Ticket) and confirm the table name.	Ticket table is created.
2	Enable auto-numbering	In the table Controls, select Auto number and set a prefix and number of digits.	Every ticket gets a unique number such as TKT0001001.
3	Add the required fields	In the Columns section, add each field with its label, type and any mandatory setting.	Table has all fields needed to store ticket data.
4	Open Form Designer	Open the table form and use Form Designer (or Configure > Form Layout).	Form Designer opens.
5	Arrange fields on the form	Drag and drop fields into sections in the order the project needs, then save.	Form is clean and easy to use.
6	Verify the update set	Confirm Project Update Set is shown as Current.	All changes are captured in the update set.

Fields Configuration (Sample)

Field	Type	Explanation
Number	String (auto-number)	Unique ticket ID generated automatically. Read-only.
Caller	Reference (User)	Person who raised the ticket. Used for the email notification.
Short description	String	One-line summary of the issue.
Description	Text (long)	Full issue details. Used for automatic classification.
Category	Choice	Broad issue area, for example Network, Hardware, Software.
Subcategory	Choice (dependent on Category)	Specific issue. Options change based on the selected Category.
State	Choice	Current status of the ticket, for example New, In Progress, Resolved.

Auto-Numbering Settings (Sample)

Setting	Sample value	Explanation
Prefix	TKT	Text placed before the number so tickets are easy to recognise.
Number of digits	7	Length of the numeric part, padded with zeros.
Starting number	1000	First number used by the counter.
Result	TKT0001000	Every new ticket gets the next unique number.

Benefits

Benefit	Why it matters
Structured storage	All tickets follow one standard format, so search and reporting are easy.
Unique identification	Auto-numbering avoids duplicates and helps tracking.
Easy to use forms	Form Designer keeps fields organised and reduces data entry errors.
Easy to maintain	Fields and layout can be changed later without rebuilding the table.

Note: Table name, field list and auto-number values above are sample values. Replace them with your project's actual values if they differ.
